

# How to release an xtpxlib component - Internal xtpxlib documentation

Erik Siegel - Xatapult - 2020-02-16

---

## 1 Instructions

The assumption is that all code and documentation is up-to-date.

1. Check the code for missing details:

- Do all important files have headers with a suitable description?
- Search globally for TBD
- Is the information in `component-info.xml` still up to date (dependencies, etc.)?
- ...

2. Git commit everything (branch `develop`)

3. Determine the new version. The system used is `major.minor[.fixcode]`.

4. Git-flow start a *new release* (Git-flow; New Release) and give it the version number as release name, prefixed with a lower-case `v` (so, for instance, `v1.0` or `v2.3.B`).

5. Edit `component-info.xml` and update the `<releases>` element with a *new* top `<release>` child. Add:

- Version number and date
- Short release description

6. Run the `doc/xpl/generate-componentdoc.xpl` pipeline to generate the GitHub pages site and other stuff.

7. Do a quick check on the generated documentation and the global `README.md` file for details (like version number/date, etc.)

8. Git commit everything to the release branch.

Usual commit message: `Release preparations vx.y`

9. Git-flow finish the release (Git-flow; Finish Release) and tag it the same as the release name (lower-case `v` with version number, `vx.y`). Optionally add some description after this, for example like in `vx.y - Bla bla bla`

Make it easy on yourself, check *Push changes to remote*.

## 2 Important remarks

- When adding a new component, update the list of active components in `global/data/componentdoc-global-parameters.xml` and re-release the `xtpxlib-webdoc` component.
- For a new component don't forget to add the correct CNAME record to the DNS (must CNAME point to `xatapult.github.io`.)
